

# Cloud Security with AWS IAM

Chrispinus Jacob

The screenshot shows the AWS IAM Policy editor interface. The left pane displays a JSON policy document for an EC2 policy. The right pane shows a modal for adding a new statement, with a 'Select a statement' dropdown and a 'Add new statement' button. The policy JSON is as follows:

```
1 v {  
2   "Version": "2012-10-17",  
3   "Statement": [  
4     {  
5       "Effect": "Allow",  
6       "Action": "ec2:*",  
7       "Resource": "*",  
8       "Condition": {  
9         "StringEquals": {  
10           "ec2:ResourceTag/Env": "development"  
11         }  
12       }  
13     },  
14     {  
15       "Effect": "Allow",  
16       "Action": "ec2:DescribeTags",  
17       "Resource": "*"  
18     },  
19     {  
20       "Effect": "Deny",  
21       "Action": [  
22         "ec2:DeleteTags",  
23         "ec2:CreateTags"  
24       ],  
25       "Resource": "*"  
26     }  
27   ]  
28 }
```

# Introducing Today's Project!

In this project, I will demonstrate how to use AWS Identity and Access Management (IAM) to control who is authenticated (signed in) and authorized (has the necessary permissions) in an AWS account. The goal of this project is to learn how to securely manage access to AWS resources by creating and managing users, groups, roles, and policies.

## Tools and concepts

Got it — here's your \*\*wrap-up in one clear line\*\*: \*\*Services I used were IAM, EC2, and the IAM Policy Simulator, and key concepts I learnt include creating users and groups, writing JSON policies with Effect, Action, and Resource, using tags and conditions to control access, and applying the principle of least privilege to protect production resources.\*\* □ Short, neat, and ready for your report!

## Project reflection

This project took me approximately 1 hour to complete. The most challenging part was making sure the IAM policy conditions were correct so that the intern could only access development instances and not production. It was most rewarding to see the policy work as expected in the IAM Policy Simulator and to learn how to safely test permissions without risking real resources.

# Tags

Tags are like labels you can attach to AWS resources for organization. Tagging helps us with identifying all resources with the same tag at once (they are useful filters when you're searching for something)

The tag I've used on my EC2 instances is called ENV. The value I've assigned for my instances are Production and Development

**Launch an instance** info

Amazon EC2 allows you to create virtual machines, or instances, that run on the AWS Cloud. Quickly get started by following the simple steps below.

**Name and tags** info

Key Info Value Info Resource types Info

Key	Value	Resource types
Name	nextwork-dev-cj	Select resource types
Env	Development	Select resource types

**Add new tag**

You can add up to 48 more tags.

**Application and OS Images (Amazon Machine Image)** info

An AMI is a template that contains the software configuration (operating system, application server, and applications) required to launch your instance. Search or Browse for AMIs if you don't see what you are looking for below.

**Console-to-Code**

Recording stopped info Reset Resume

**Recorded actions (3)**

- Generate CFN YAML
- Copy CLI
- Code generation by Amazon Q

Type: All types info Find actions by operation

Operations	Type	Creation time
EC2 / Launch Inst...	Write	Wed Jun 04 2025
RunInstances	Write	Wed Jun 04 2025
AuthorizeSecurityGroup	Write	Wed Jun 04 2025
CreateSecurityGroup	Write	Wed Jun 04 2025

# IAM Policies

IAM policies are a set of rules that define who can do what in an AWS account. They specify which actions are allowed or denied on which AWS resources. By attaching policies to users, groups, or roles, you control what permissions those identities have, ensuring secure and organized access management.

## The policy I set up

For this project, I've set up a policy using...JSON

I have created an IAM policy that allows the policy holder (for example, the Nextwork intern) to perform any action on EC2 instances that are tagged with Environment = Development. This means they can start, stop, reboot, or modify development instances freely. For all other EC2 instances (for example, production instances), they can only view information (such as describing instances) but cannot perform any operations like starting, stopping, or modifying them.

## When creating a JSON policy, you have to define its Effect, Action and Resource.

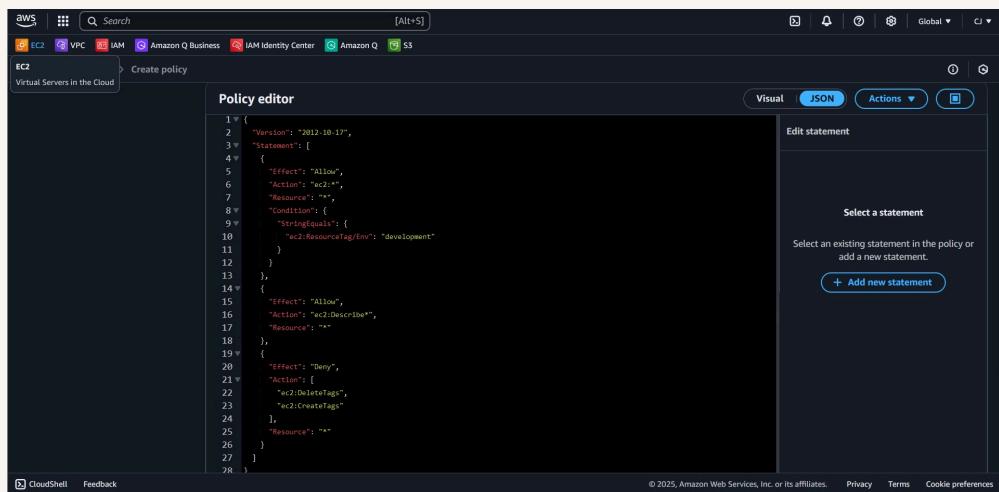

The Effect, Action, and Resource attributes of a JSON policy means...whether or not the policy is allowing/denying the action. (effect) , what policy holder can /not do . (Action) . AWS Resources that the policy holder relates to. (Resource)

# My JSON Policy

The screenshot shows the AWS IAM Policy editor interface. The left pane displays a JSON policy document for EC2 resources. The right pane shows a visual representation of the policy and a section for adding new statements.

```
1 Version: "2012-10-17",
2 Statement: [
3   {
4     "Effect": "Allow",
5     "Action": "ec2:*",
6     "Resource": "*",
7     "Condition": {
8       "StringEquals": {
9         "ec2:ResourceTag/Env": "development"
10      }
11     }
12   },
13 ],
14 {
15   "Effect": "Allow",
16   "Action": "ec2:Describe*",
17   "Resource": "*"
18 },
19 {
20   "Effect": "Deny",
21   "Action": [
22     "ec2:DeleteTags",
23     "ec2:CreateTags"
24   ],
25   "Resource": "*"
26 }
27 ]
28
```

# Account Alias

An account alias is simply nickname for aws account instead of the long name

Creating an account alias took me... 30 secs Now, my new AWS console sign-in URL is... uses alias instead of my account id

Preferred alias

A text input field containing the value "nextwork-alias-cj".

Must be not more than 63 characters. Valid characters are a-z, 0-9, and - (hyphen).

New sign-in URL

<https://nextwork-alias-cj.signin.aws.amazon.com/console>

i IAM users will still be able to use the default URL containing the AWS account ID.

[Cancel](#) [Create alias](#)

# IAM Users and User Groups

## Users

IAM users are individual identities created within AWS IAM to represent a person or application that interacts with AWS resources.

## User Groups

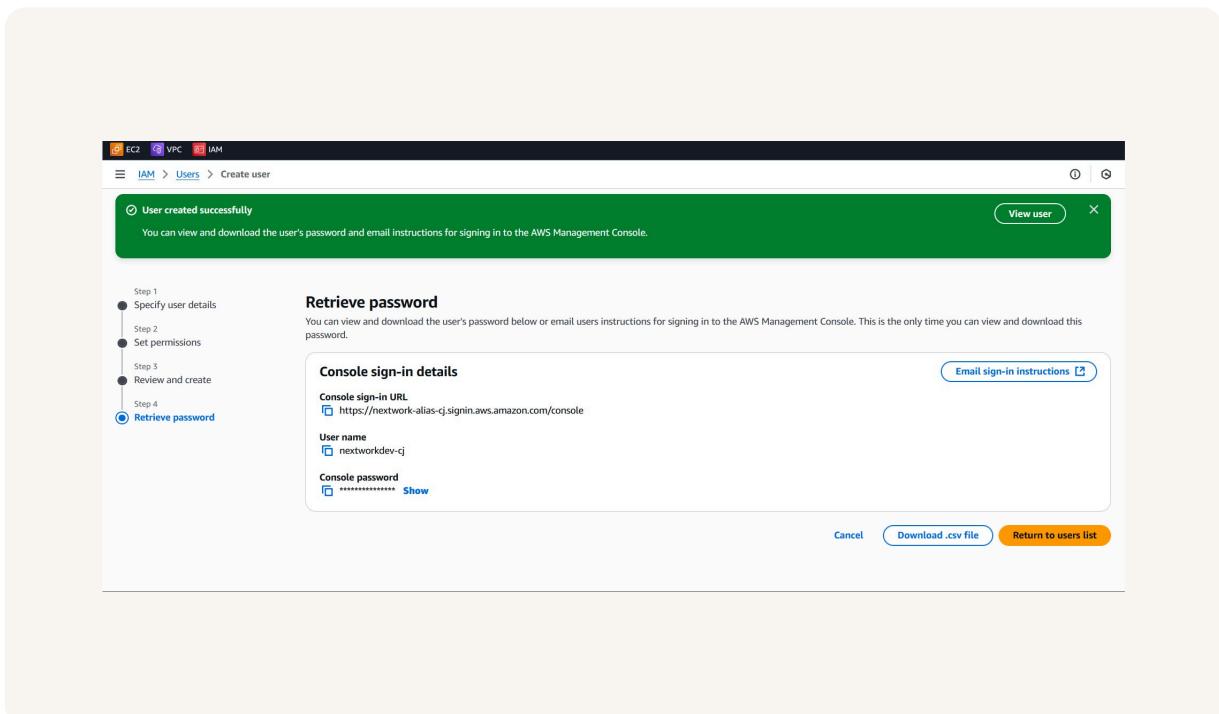

IAM user groups are like folders that collect multiple IAM users together. This allows you to apply permissions at the group level instead of managing permissions for each user one by one. Any permissions you attach to a group automatically apply to all users in that group.

I attached the IAM policy I created (which allows full access to development instances and read-only access to others) to the Dev user group. This means any IAM user added to the Dev group will automatically get the same level of access defined by the policy. So, all developers in this group can work on development resources but cannot make changes in the production environment.

# Logging in as an IAM User

The first way is...AWS provides user sign-in link, username, and (optionally) a temporary password after creation. You can manually copy and send

Once I logged in as the intern IAM user, I noticed that the user could not see some items or panels in the AWS Management Console. This is because we only granted permissions to manage development instances. The IAM user does not have permissions for other AWS services or resources, so those parts of the console are hidden or inaccessible.

# Testing IAM Policies

I tested my JSON IAM policy by logging in as the intern IAM user and trying to perform actions on both development and production EC2 instances. I confirmed that the intern could start, stop, and manage instances tagged as Development but could only view production instances and could not stop or modify them. When I attempted to stop a production instance, I received an error message as expected — proving that the policy is correctly blocking unauthorized actions.

## Stopping the production instance

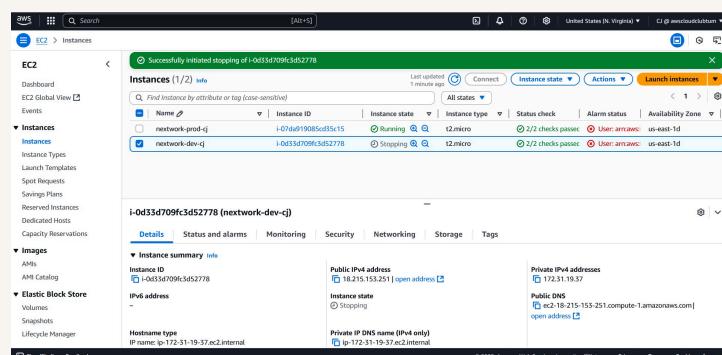

When I tried to stop the production instance while logged in as the intern IAM user, I received an error message. This happened because the IAM policy attached to the intern explicitly denies any actions on resources tagged as production. The intern is only allowed to manage development instances and has no permissions to perform actions (like starting, stopping, or modifying) on production resources.

# Testing IAM Policies

## Stopping the development instance

Next, when I tried to stop the development instance while logged in as the intern IAM user, the action succeeded as expected. This was because the IAM policy explicitly allows full control (ec2:\*) for instances tagged with Environment = Development. This confirms that the user has the correct permissions to manage development resources, as intended.

# The IAM Policy Simulator

The IAM Policy Simulator is a tool provided by AWS that lets you test and troubleshoot IAM policies without actually performing actions on real AWS resources.

## How I used the simulator

I set up a simulation for my intern IAM user to test whether they could delete tags and stop instances for both development and production EC2 instances, and the results showed that the user was allowed to stop instances in the development environment but denied from stopping production instances or deleting tags on either environment.

The screenshot shows the IAM Policy Simulator interface. On the left, the policy document is displayed:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:Stop",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "ec2:ResourceTag/Env": "development"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:Describe",
      "Resource": "*"
    },
    {
      "Effect": "Deny",
      "Action": [
        "ec2:DeleteTags",
        "ec2:CreateTags"
      ],
      "Resource": "*"
    }
  ]
}
```

The right side shows the results of the simulation for the Amazon EC2 service:

Service	Action	Resource Type	Simulation Resource	Permission
Amazon EC2	StopInstances	instance	*	allowed 1 matching statements.
Amazon EC2	DeleteTags	not required	*	denied 1 matching statements.

Below the table, a note says: "Resource - You can specify the resource and context keys used to simulate this action. By default the simulation resource is \*." There is also a "Add Resource" button.
